Tardigrades: from genestealers to space marines

Dudkovskaya A., Oshchepkova P.

Abstract

A tiny water bear with eight legs and covered in tough cales, which can endure conditions that don't even exist on Earth, such as vacuum, absolute zero and γ -radiation at doses between 1.0-9.0 kGy, is a tardigrade. Their extreme tolerance raise from the ability to dry without critical DNA damage, unlike other animals. The nature of preventing DNA distruction could unveil new DNA protection mechanism. Here we analysed tandem mass spectrometry data obtained from isolated chromatin fraction of Ramazzottius varieornatus to understand how tardigrades' DNA is keeping from radiation-induced damages. We find 5 proteins that can provide this protection function, and one of them is already described in Ramazzottius varieornatus as Damage suppressor protein (Dsup).

1 Introduction

Tardigrades are a species of microscopic invertebrates. They have four pairs of legs, their size is about 0.1-1.5 mm. Tardigrades have digestive, excretory, nervous and reproductive systems, however, their respiratory system is dermal. Tardigrades are of the greatest interest due to their incredible endurance. When unfavorable conditions occur, they are able to fall into a state of suspended animation for years, and when favorable conditions occur, they quickly revive. Tardigrades survive mainly due to the called anhydrobiosis, drying. They are able to stay alive after extreme temperature from -273 C° to 100 C° , high pressure (7.5 GPa), exposure to high dose of irradiation and direct exposure to open space.

We are interested in causes of their endurance to high doses of exposure. There are already exist some articles about genome studies of Tardigrades [1], [2]. Most of them provide that there is no extensive Horizontal gene transfer.

We investigate the endurance of *Ramazzottius varieornatus*, one of the most stress-tolerant species of Tardigrades. We are interested in proteins. located in nuclear, because of their location we can suppose that their functions are to protect DNA from damages and repair it. We do functional annotation by looking for homologous proteins and conserved domains to attribute potential functions to the genes and proteins that we found.

2 Methods

Data acquisition

We use a sequence of the YOKOZUNA-1 strain of of the Ramazzottius varieornatus. All data is avaliable here.

Structural annotation, physical localization prediction and BLAST search We use AUGUSTUS [3] for functional annotation. Then we extract protein sequences. To find protein located in nuclear we analyzed the extracted proteins using tandem mass spectrometry. All data is avaliable here. Then we do a local alignment-based search using

blast [4]. We create a database and perform the search usind default options. To extract proteins of interest from the initial file we use samtools [5], esspesialy faidx utility. For prediction of localization of our proteins from mass-spectrometer data we use WoLF PSORT [6]. Then we BLAST proteins that can possible locate in nuclear to find similar proteins in other organisms.

Pfam prediction

Also we try to predict the function of proteins even if we can't find orthologous sequences in databases with Blast. To do this we use HMMER [7] to search for our protein sequences. This tool use HMM profiles for various protein domains and motifs.

3 Results

After qualifying peptides from mass-spectrometry data and structural annotation by using AUGUSTUS, we find 34 unique proteins. Then we use Wolfpsrort for localization prediction. Futher we research only proteins that have predicted localisation in nuclear with some score greater then zero. The results are provided in the Table 1.

Further we use blast to find homology proteins and try to predict function of proteins. Here we choose only proteins that have other organisms, not Tardigrades. The results are provided in the Table 2.

Also we try to find some functional motifs, that maybe can explain the endurance of *Ramazzottius varieornatus* by using HHMER. HHMER found finctional motifs only in 8 proteins. Proteins names and prediction of their functionality are presented in the Table 3.

4 Discussion

During our research we find 17 proteins that may locate in nuclear of Tardigrades cells. We try to explore their functions by finding homology genes and functional motifs. So we have some predicted functions of these proteins. The results are provided in the Table 4.

Table 4: Predicted functions of proteins

The filaggrin-like protein encoded by this gene is upregulated by calcium, proteolyzed by calpain 1, and is involved in epithelial homeostasis. RNA and ssDNA-binding protein that may play specific roles during transcription initiation at distinct promoters. Can enter the preinitiation complex together with the RNA polymerase II (Pol II). g11513.t1 g11513.t1 g11513.t1 g11513.t1 g11513.t1 g11513.t1 g11513.t2 DNA/RNA-binding protein that plays a role in various cellular processes such as transcription regulation, RNA splicing, RNA transport, DNA repair and damage response. g11960.t1 g11513.t1 g11513. The EF-hand consists of two alpha helices linked by a short loop region (usually about 12 amino acids) that usually binds calcium ions. EF-hands also appear in each structural domain of the signaling protein calmodulin and in the muscle protein troponin-C. Component of a Polycomb group (PcG) multiprotein PRC1-like complex, a complex class required to maintain the transcriptionally repressive state of many genes, including Hox genes, throughout development. PcG PRC1-like complex acts via chromatin remodeling and modification of histones; it mediates monoubiquitination of histone H2A 'Lys-119', rendering chromatin heritably changed in its expressibility. g5927.t1 Catalytic Activity, acetyl-CoA + D-glucosamine 6-phosphate = CoA + H+ + N-acetyl-D-glucosamine 6-phosphate. Catalyzes the hydrolysis of phosphoadenosine phosphate (PAP) to adenosine		•
response. g2203.t1 Enzyme that hydrolyses the glycosidic bond between two or more carbohydrates, or between a carbohydrate and a non-carbohydrate moiety. 		monophosphate (AMP).

g7861.t1	ATP-dependent annealing helicase that binds selectively to fork DNA relative to ssDNA or dsDNA and catalyzes the rewinding of the stably unwound DNA. Rewinds single-stranded DNA bubbles that are stably bound by replication protein A (RPA). Acts throughout the genome to reanneal stably unwound DNA, performing the opposite reaction of many enzymes, such as helicases and polymerases, that unwind DNA.
g8312.t1	Plays a role in vesicle-mediated protein trafficking to lysosomal compartments including the endocytic membrane transport pathways.

Due to these results we have five proteins that are most likely responsible for DNA protection and reparation: g11806.t1, g14472.t1, g16318.t1, g16368.t1, g7861.t1. Thus these proteins are needed to be studied in more details.

Also, when we use BLAST, we find that one protein, g14472.t1, can be aligned to Tardigades protein Damage suppressor (Dsup). We found that there is already exists a research showing that it is a unique tardigrade protein that helps repair and protect DNA from radiation [8].

For further studies there is a classical way to test our findingse - gene knockout, but this approach could be tricky due to complex object, there are no established techniques for genetic engineering of tardigrades. Also, to detect that protein is located in the nucleus the nreen fluorescent protein may be used as a reporter gene.
